

Website traffic analysis

Problem Statement: web traffic analysis

Objective:

Web Traffic Analysis helps to gain insights about visitors and their behavior on our websites to deliver better results. BigQuery and Google Analytics provide you the information needed to improve the website, and make it the best it can be

Challenges (Anticipated):

- Issues such as missing tracking code on web pages, data sampling with skewed results, ad block services that filter out valuable analytics data, and incorrect data filters are only a few examples of where you things can go wrong.
- Insufficient Knowledge

Design Thinking (Planned):

Define:

Building on the insights gained during the empathize phase, we will define the specific problem at hand. This involves crystallizing the need for a robust and adaptive fraud detection system that can effectively differentiate between legitimate and fraudulent transactions.

Ideate:

Armed with a deep understanding of the problem, we will engage in a creative brainstorming process. This will involve generating a multitude of ideas and potential solutions. These could range from leveraging machine learning models to exploring anomaly detection techniques and even considering rule-based systems. The goal is to devise a comprehensive fraud detection strategy.

Prototype (Planned):

The prototype phase involves the practical implementation of our website traffic analysis system. We will employ a carefully curated dataset and select a machine learning model to begin the initial development. This prototype will serve as the foundation for the subsequent phases of the project. We are using JavaScript as prototype.

Test (Planned):

The prototype will be rigorously tested under various scenarios and conditions. This testing phase is crucial for evaluating the system's performance and identifying areas that require refinement. Similarweb is a popular tool for getting data about web traffic and performance. This tool is really simple to use – you just enter a website URL and Similarweb gives you information about the site's organic rankings, competitors, marketing channels and more

Iterate (Planned):

Based on the results obtained from testing, the system will undergo iterative improvements. This could involve fine-tuning the algorithms, optimizing parameters, and enhancing the system's adaptability to emerging website traffic. The iterative process ensures that the system evolves to meet the dynamic nature of website traffic.
